IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

Applicant(s): R. BRADBURY, ET AL.
Serial No.: 09 / 825,944
Filed: APRIL 5, 2001
Title: "CONTAINER UNLOADING APPARATUS".

LETTER CLAIMING RIGHT OF PRIORITY

Assistant Commissioner for
Patents
Washington, D.C. 20231

MAY 23, 2001

Sir:

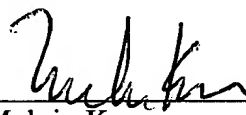

Under the provisions of 35 USC 119 and 37 CFR 1.55, the applicant(s) hereby claim(s)
the right of priority based on:

Great Britain Patent Application No. 9821665.8
Filed: OCTOBER 5, 1998

A certified copy of said Great Britain Patent Application is attached.

Respectfully submitted,

ANTONELLI, TERRY, STOUT & KRAUS, LLP

INVESTOR IN PEOPLE

The Patent Office
Concept House
Cardiff Road
Newport
South Wales
NP10 8QQ

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

I also certify that the attached copy of the request for grant of a Patent (Form 1/77) bears an amendment, effected by this office, following a request by the applicant and agreed to by the Comptroller-General.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Signed

Andrew Gersey

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

Container Handling Apparatus

This invention relates to container handling apparatus, particularly apparatus for unloading containers of rod-like articles such as cigarettes or cigarette filter rods.

In the cigarette industry it is known to transport cigarettes and cigarette filter rods in trays, each of which typically contains 4,000 articles, at least partly between a producing machine, such as a cigarette or filter rod making machine, and a receiving machine, such as a cigarette packing machine or a filter rod assembling machine. In the case of cigarettes containers may be unloaded at the packing machine or upstream of it for conveyance to the packing machine in a multi-layer stream of articles. In the case of filter rods, although the containers may similarly be unloaded at the filter rod assembling machine, it is common to unload them at or upstream of a pneumatic filter rod distributor unit, from which filter rods are pneumatically conveyed to the filter rod assembling machine. Again, the filter rods may be conveyed in a multi-layer stream of articles subsequent to unloading. The present invention is particularly, but not exclusively, concerned with apparatus suitable for unloading trays in any of these situations.

According to a first aspect of the invention apparatus for unloading containers for rod-like articles comprises carrier means for receiving a full container in a receiving position in a first orientation, and means for moving the carrier to an unloading position at which the carrier is in a second orientation, the moving means including means for translating the carrier and means for rotating the carrier. The transferring means and rotating means are preferably independently controlled, so that relative translation and rotation between the receiving and unloading positions may be varied. Preferably the translating means is linear. The receiving and unloading positions may be substantially at the same level, eg so that the path of the translating means is substantially horizontal. Preferably the rotating means is effective to rotate the carrier so that a container is rotated between said first and second orientations, eg through substantially 180° so that a container is upright at the receiving position and inverted at the unloading position.

In a preferred arrangement the translating and rotating means are reversible. In this case an unloaded container may be moved from the unloading position to a position intermediate the unloading and receiving

1 positions, from which intermediate position transfer means may remove
2 the unloaded container, eg in a direction transverse to the path of said
3 translating means.

4 In a preferred arrangement the carrier means comprises a
5 carriage slidable between the container receiving and unloading
6 positions and a rotatable carrier mounted on the carriage.

7 The location of the unloading position may be determined by
8 reference to the contents of the container, eg the lengths of the rod-like
9 articles, relative to a fixed datum position.

10 Means may be provided for advancing containers to the receiving
11 position, eg on substantially horizontal conveyor bands. Particularly
12 where the containers are advanced in abutment at least adjacent the
13 receiving position, it is preferred that said translating and rotating means
14 are arranged such that initial movement of a container away from the
15 receiving position includes both translational and rotational components:
16 in this way a container may be removed from a flat surface containing an
17 abutting line of containers upstream of the receiving position.

18 Preferably at least one of the translating and rotating means
19 includes means for moving the carrier means to a preferred position
20 following a stoppage. Such means may include means for interrogating
21 at least one detector for the position of the carrier means and
22 subsequently moving the carrier means to a reference position in a
23 direction determined by the results of said interrogation.

24 According to another aspect of the invention apparatus for
25 unloading containers of rod-like articles comprises means for delivering
26 a container to an unloading position at which articles are unloaded
27 through an open end of the container, and means for conveying
28 unloaded articles away from the unloading position along a path,
29 wherein the conveyor means extends substantially across said open end
30 at said unloading position except at said path. Preferably the extent of
31 said path is substantially less than the extent of said open end, so that
32 the conveyor means extends across a substantial part of the width of
33 said open end. Preferably the container is so orientated at said
34 unloading position (eg inverted) that said open end and said conveyor
35 means extend substantially horizontally with said conveyor means
36 immediately below said open end. In this way articles unloaded from the
37 container, eg by release of a plate confining the articles in the container,
38 have a very small distance to fall onto the conveyor means. The level of

1 articles already unloaded in said path may be controlled such that it is
2 substantially the same as that of said conveyor means. In a preferred
3 arrangement the conveyor means comprises endless band conveyor
4 means, preferably opposed bands defining said path between their
5 confronting ends.

6 By arranging that the conveyor means is substantially immediately
7 adjacent the open end of the container at the unloading position, the
8 distance through which articles have to move at the unloading position
9 from the container is both small and determinate, thereby eliminating or
10 substantially reducing the disadvantages experienced in some prior art
11 arrangements, namely that relatively complicated mechanisms are
12 needed to maintain a surface of unloaded articles relatively flat to receive
13 the next unloaded batch from a container and/or that there is a risk of
14 unloaded articles becoming misaligned as they fall through an excessive
15 distance onto that surface after unloading.

16 According to a further aspect of the invention apparatus for
17 unloading containers of rod-like articles comprises means for delivering
18 a container to an unloading position, and means for conveying unloaded
19 articles away from the unloading position, wherein the conveying means
20 is driven at a first relatively high speed during a first phase during which
21 a first, major part of the contents of a container are unloaded and at a
22 second, lower speed during a second phase during which the remainder
23 of the contents of a container are unloaded. Preferably the transition
24 between said first and second phases takes place dependent on a signal
25 from detector means sensing the level of articles in or from an unloading
26 container. Preferably the conveyor means includes first conveyor means
27 immediately adjacent the unloading container and second conveyor
28 means downstream of said first conveyor means for conveying away a
29 multi-layer stream of articles. The ratio of speeds of the first and second
30 conveyor means preferably differs in said first and second phases: in
31 one arrangement wherein the first conveyor means comprises
32 confronting band conveyors and the second conveyor means comprises
33 a further band conveyor the ratio of the speeds of the first conveyor
34 means to the second conveyor means is 55% in the first phase and
35 105% in the second phase. It will be appreciated that these ratios will
36 vary at least dependent on the height of any stream being conveyed by
37 the second conveyor means.

38 Further detector means may be provided for stopping the

1 conveying means substantially when the contents of a container have
2 been unloaded. The second detector means may comprise a level
3 detector arranged in the path of unloading articles immediately
4 downstream of the unloading position.

5 The conveying means may convey a stream of articles to a
6 variable capacity reservoir. Articles unloaded from a container may be
7 received in the reservoir, which may have associated with it sensors for
8 detecting the relative capacity of the reservoir and for controlling the
9 conveying means in accordance with a signal derived from the sensor.

10 The various aspects of the present invention may be embodied in
11 common apparatus.

12 The invention will be further described, by way of example only,
13 with reference to the accompanying diagrammatic drawings, in which:

14 Figure 1 is a perspective view of part of an apparatus for
15 unloading trays of rod-like articles,

16 Figure 2 is a perspective view of part of the apparatus of Figure 1
17 with some parts in different operative positions,

18 Figure 3 is a side view of the apparatus as shown in Figure 2,

19 Figure 4 is a side view, similar to Figure 3 but with some parts in
20 different positions,

21 Figure 5 is a schematic side view showing relative operative
22 positions of the apparatus of Figure 1,

23 Figure 6 is a front view of the apparatus, in the direction of arrow
24 VI in Figure 3,

25 Figure 7 is a detail plan view of part of the apparatus of Figure 1,
26 and

27 Figure 8 is a perspective view of part of the apparatus of Figure 1,
28 showing details of a drive arrangement for a tray carriage.

29 Figure 1 shows tray handling apparatus for delivering full trays 10
30 containing rod-like articles to an unloading position 10A at which the
31 trays are inverted to unload the articles to a conveyor system 12 (Figure
32 6) in which the articles are conveyed away in a multi-layer stream of
33 articles moving transverse to their lengths. Full trays 10 are delivered in
34 an upright condition to a pick-up position 10B by an upper conveyor
35 comprising laterally spaced bands 14. As shown in Figure 5, trays 10 are
36 normally disposed in abutment upstream of the tray in position 10B,
37 which tray is maintained stationary by a pivoted latch 16 (Figure 3), so
38 that the bands 14 may continue to operate with an abutting line of

1 stationary trays maintained up to the position 10B by the latch.

2 Referring also to Figure 8, a tray carriage 18 is supported by and
3 slidably movable relative to a pair of slideways comprising linear actua-
4 tors 20 which extend parallel to the bands 14 from positions laterally
5 adjacent the pick-up position 10B. The carriage 18 comprises a frame 19
6 spanning and movable along the actuators 20 between positions adja-
7 cent the positions 10A and 10B under action of a servo drive motor 22
8 (Figure 2). The frame 19 is attached to load plates 21 of the actuators 20
9 such that the carriage 18 is cantilevered beyond the travel limit 25 of the
10 actuators when it is in the unloading position 10A. The motor 22 oper-
11 ates both actuators 20 through a common shaft 23.

12 A tray carrier 24 is pivotally supported at 26 on the carriage 18
13 and is pivotable, under action of a servo drive motor 28, through 180°
14 between a position at which it can receive an upright tray 10 at the
15 position 10B and a position at which it maintains an inverted tray at the
16 unloading position 10A. Referring to Figures 1-3, the tray carrier 24
17 comprises a backplate 30, against which the rear face of a tray 10 is
18 located when a tray is in place in the carrier, and a pair of pivoted side
19 clamps 32 which operate, under action of a pneumatic cylinder 34
20 operating through a rotor 36 and a pair of links 38, to clamp a tray in
21 place on the carrier. The clamps 32 have the added capability of pulling
22 a slightly misaligned tray into alignment on the carrier 24 as they clamp
23 the tray. Also mounted on the carrier 24 is a release plate 40 which, in
24 the position shown in Figure 1, covers the open top of a tray received
25 from the pick-up position 10B and is slidably supported by guides 42 so
26 as to be movable, under action of a pneumatic cylinder 44, into a retrac-
27 ted position following insertion of a tray 10 at the unloading position 10A,
28 as shown in Figure 2.

29 As will be explained hereinafter, trays 10 which have been
30 unloaded are returned by the tray carrier 24 to an upright condition in a
31 position intermediate positions 10A and 10B. An empty tray transfer
32 mechanism 46 receives each empty tray and deposits it on an empty
33 tray conveyor comprising laterally spaced bands 48 located below the
34 bands 14. The mechanism 46 comprises a tray support 50, on which the
35 base of the tray 10 is received, and a clamp 52 which is pivoted to the
36 support about a horizontal axis and movable between a position clear of
37 the support to allow reception of a tray from above and the position
38 shown in the drawings, in which it engages the upper surface of the

1 base of the tray to locate it on the support. The support 50 is mounted
2 on a four bar (parallel bar) linkage 54 so as to be maintained in the same
3 orientation as it is moved between a tray receiving position (above the
4 position shown in Figure 4) and a tray delivering position, as shown in
5 Figures 1-3, in which the empty tray is deposited on the bands 48 which
6 subsequently convey the tray away. The linkage 54 is pivotally mounted
7 to the support 50 and to a fixed backplate 60, and is operated by an
8 actuating rod 56 and a linear actuator with braking capability in the form
9 of an Acme lead screw 58, itself pivotally mounted to a fixed part 62 of
10 the apparatus. The connection between the actuating rod 56 and the
11 linkage 54 is by way of a pivotal mounting in a bracket 64 connected to
12 the linkage: in Figure 4 the end of the rod 56 is shown separated from
13 the bracket 64 but in operative condition these would be connected, as
14 shown in Figure 3.

15 In operation, trays 10 filled with rod-like articles are advanced by
16 the bands 14 in the direction indicated in Figure 1. A leading tray 10 is
17 stopped at the position 10B, engaged by the latch 16 (Figure 3).
18 Normally trays 10 accumulate in line abutment on the bands 14 behind a
19 tray in position 10B, as indicated in Figure 5.

20 The carriage 18 is advanced towards the position 10B with the
21 carrier 24 in an upright condition and the tray clamps 32 in retracted
22 positions. A leading part of the carriage 18 has a part (not shown) adap-
23 ted to cooperate with the inclined leading face of the latch 16 so as to
24 pivotally displace it when the carriage reaches the position 10B and
25 allow the leading full tray 10 to be engaged by the carrier 24. At this time
26 the clamps 32 are operated to grip the tray 10. The release plate 40 may
27 be moved to an extended position to cover the open top of the tray at
28 any time after a tray has emptied and before the next full tray begins to
29 be turned over: one currently preferred timing is to extend the plate
30 when the carriage is in position 10C just prior to delivery of an empty tray
31 to the empty tray transfer mechanism 46.

32 After a tray 10 has been located on the carrier 24 by the clamps
33 32, the motors 22 and 28 operate substantially simultaneously so that
34 initial movement of the tray from the position 10B includes linear and
35 rotational components. This facilitates removal of a tray from the
36 position 10B when there is an immediately abutting following tray on the
37 bands 14. After a leading tray has been withdrawn from the position 10B
38 the latch 16, released from its displacement by the carriage 18, returns

1 under action of a counterweight to its previous position so that the next
2 tray advanced by the bands 14 is stopped at position 10B.

3 The carriage 18 moves away from the position 10B and the carrier
4 24 is rotated through 180° to invert the tray 10, such movement and
5 rotation being complete at the unloading position 10A. The motors 22
6 and 28 are independently controlled: hence the relative rates (including
7 acceleration and deceleration) at which the carriage 18 may be moved
8 and the carrier 24 rotated are independently controllable. In this way, it is
9 possible to adjust the positions of the carriage 18 at which the carrier 24
10 assumes given rotational positions: although initiating linear and rota-
11 tional movement at the same time at the position 10B is preferred, linear
12 and rotational movements may start at different times and proceed
13 continuously or intermittently at different rates, eg the start of rotational
14 movement could be delayed until some movement of the carriage 24 has
15 occurred or rotational movement of the carrier 24 may be completed in
16 stages so that after an initial movement the carrier is maintained in a
17 fixed inclined position while the carriage moves for some distance. The
18 relative rates and positions at which linear and rotational movements
19 take place may be varied in accordance with parameters associated with
20 the articles contained in the trays: for example, cigarettes are more
21 delicate than filter rods and so may not tolerate such rapid inversion of a
22 tray. Another possibility is that the relative rates of linear and rotational
23 movement may be varied in accordance with the lengths of the articles
24 contained in the trays.

25 At the unloading position 10A the release plate 40 is withdrawn,
26 allowing the articles contained in the tray to descend to the conveyor
27 system 12. The apparatus includes a transparent stationary front plate 66
28 (Figure 5) at the unloading position 10A and extending also at the front
29 of the conveyor system 12 to confine the articles if necessary.

30 When unloading of the contents of a tray at the unloading
31 position 10A is complete the carriage 18 is retracted and the carrier 24
32 rotated to an upright position during movement to the position 10C
33 (Figure 5), intermediate the positions 10A and 10B. As before, relative
34 rotational and linear movements may be adjustable: as the tray is empty
35 during this phase of movement, no consideration as to imposition of
36 excessive forces on delicate articles is necessary.

37 At the position 10C the empty tray 10 is delivered to the empty
38 tray transfer mechanism 46. The linkage 54 is raised so that the support

1 50 abuts the bottom of the tray 10 and the clamp 52 is pivoted upwards
2 and subsequently down onto the upper face of the bottom of the tray to
3 clamp it to the support. The pivoted clamps 32 on the carrier 24 are
4 retracted to release the tray, which is subsequently moved down on the
5 support by the linkage 54 until it rests on the upstream ends of the
6 bands 48 in position 10D (Figure 5). The clamp 52 is retracted just prior
7 to placement of the empty tray 10 on the bands 48 so that the empty tray
8 can be conveyed away from position 10D by the bands. During the initial
9 part of movement of the empty tray transfer mechanism 46, as soon as
10 the tray is clear of the carrier 24, the carriage 18 is advanced from posi-
11 tion 10C to position 10B to pick up the next full tray 10 and commence
12 the next cycle.

13 It will be apparent that the position of the carriage 18 is critical to
14 correct operation of the unloading apparatus. Thus, after any stoppage,
15 eg disconnection from an electrical supply, it is arranged that the
16 carriage 18 is moved by the motor 22 to a preferred definite position
17 from which subsequent movements are made as determined by the
18 control system. As shown in Figure 7, in order to achieve this the
19 carriage 18 carries with it a sensor bar 94 which moves along a path
20 parallel to and adjacent one of the actuators 20 as the carriage moves.
21 The sensor bar 94 is stepped so as to comprise a first, longer portion 96
22 and a second, shorter portion 98. Fixed to the (stationary) frame of the
23 actuator 20 and just below the path of the bar 94 are three sensors 100,
24 102, 104, each capable of detecting when the bar 94 is located above
25 the sensor.

26 The carriage 18 is movable between end positions 18A and 18B
27 as shown in Figure 7. Position 18A is beyond the tray unloading position
28 10A and position 18B is beyond the full tray pick-up position 10B.
29 Sensor 100 is located so that it is just covered by the bar 94 at position
30 18B, as indicated in Figure 7. Sensor 104 is located so that it is just
31 covered by the shorter portion 98 of the bar 94 at position 18A. At an
32 intermediate position 18E, approximately half way between positions 18A
33 and 18B, the sensor 102 is just covered by the end of the longer portion
34 96 of the bar 94 when the carriage 18 is in position 18B; in other words,
35 the length of the portion 96 just exceeds the distance between sensors
36 100 and 102.

37 In operation, after any stoppage sensor 102 is used to determine if
38 the carriage 18 is to the left (as viewed in Figure 7) of position 18E (the

1 sensor is covered by the portion 96) or if it is to the right (the sensor is
2 uncovered). Subsequently, in either case the carriage 18 is moved
3 towards position 18E, and the switching transition (between sensor 92
4 being covered and uncovered or vice versa) used to determine when
5 that position is reached. At that position the movement is stopped and
6 the absolute position of the carriage 18 is reestablished, at the known
7 reference position 18E. The carriage 18 can then perform a precisely
8 controlled movement to any position along its path.

9 If the carriage 18 reaches position 18A or 18B, each of which is
10 beyond the respective end of the normal operating range of movement
11 of the carriage, sensor 100 or 104 detects this and signals a fault.

12 It will be appreciated that position of the carrier 24 is similarly
13 critical to correct operation of the apparatus. A precisely analogous
14 control system is provided to move the carriage 24 into a reference rota-
15 tional position, the only difference being that the parts corresponding to
16 the sensor bar 94 and the corresponding sensors are arranged on an
17 arcuate path about the axis 26.

18 In the tray unloading position 10A the position at which the carri-
19 age 18 stops may be adjustable: in this way it is possible, if required, to
20 operate the apparatus so that the unloading position is determined by
21 reference to the articles contained in the tray, eg so that the free ends of
22 the articles are located a fixed distance from the plate 66, instead of by
23 reference to parts of the tray or apparatus itself. The position at which
24 the carriage 18 stops at the pick-up position 10B may be similarly
25 adjustable: in particular this may need to be varied if for instance a
26 different style of tray 10 were used necessitating a different tray clamping
27 mechanism.

28 Referring to Figure 5, the conveyor system 12 downstream of the
29 unloading position 10A comprises confronting endless bands 70 having
30 horizontal upper runs arranged substantially immediately below the
31 unloading position 10A. Extending from the opening between the ends
32 of the bands 70 is a vertical channel 72 leading to a further conveyor
33 band 74 extending horizontally towards a variable capacity reservoir 76.
34 An upper band 78 is arranged above the band 74 along part of its length.

35 The reservoir 76 comprises an arcuate top plate 80 and an
36 arcuate side plate 82 arranged opposite the downstream end of the
37 conveyor band 74 and pivotable about an axis 84 so as to be movable
38 between the position shown in full lines in Figure 6 (in which the

1 reservoir 76 is substantially full) and the position 82A shown in dotted
2 lines (in which the reservoir is substantially at its minimum capacity). At
3 its lower end the reservoir 76 has an outlet 86 leading downwards onto a
4 horizontal conveyor band 88. A top band 90 is arranged above the
5 downstream end of conveyor band 88.

6 Rod-like articles unloading from a tray at position 10A are urged
7 by conveyor bands 70 into channel 72. A substantially continuous
8 multi-layer stream of articles is received in the channel 72 and delivered
9 by way of bands 74 and 78 to the variable capacity reservoir 76. The
10 pivoted plate 82 is lightly counterweighted so that it is urged in a
11 clockwise direction as shown in Figure 6 to maintain slight pressure on
12 the articles in the reservoir so as to confine the articles and prevent the
13 occurrence of voids. Articles are withdrawn from the outlet 86 of the
14 reservoir by the bands 88 and 90. A stream of articles delivered by the
15 bands 88, 90 may be conveyed to further processing apparatus. For
16 example, where the articles are cigarettes, the further processing appara-
17 tus may be a cigarette packing machine; where the articles are filter
18 rods, the apparatus may be a distributor for pneumatically conveying the
19 filter rods to a filter cigarette assembling machine.

20 The bands 70, 74 and 78 are controlled separately. The bands 70
21 run at the same speed as each other, as do the bands 74, 78 and 88, 90
22 respectively. In various operative conditions the speeds of the bands 70,
23 74 and 88 depend on the level of fill (volume) of the reservoir 76 and on
24 the status of upper and lower article level detectors 92, 94 located
25 respectively at and adjacent the unloading position 10A. Each of the
26 detectors 92, 94 may comprise opto-electronic means which senses the
27 presence of adjacent articles, eg by sensing interruption of a beam of
28 radiation: such means are well known in the cigarette industry. The
29 upper detector 92 is positioned immediately above the channel 72 at a
30 height corresponding to a level reached by the articles when a tray at
31 unloading position 10A is about 80% unloaded. The lower detector 94 is
32 positioned at the upper end of the channel 72 just below the level of the
33 bands 70.

34 While the majority of the contents of a tray at the unloading posi-
35 tion 10A are being delivered to the conveyor system 12 the detector 92
36 is covered, ie detects articles. In this situation, the bands 70 are run at a
37 speed which bears a fixed relationship to the speed for the time being of
38 the band 74. A preferred ratio is that the bands 70 have a speed which is

1 set at about 55% of the speed of the band 74. If the reservoir or volume
2 value is less than a predetermined high value (eg corresponding to 85%
3 of maximum capacity) the band 74 is run at a fixed high speed so as to
4 unload the tray rapidly. With filter rods, for example, this speed may be
5 as high as that corresponding to a flow rate of 48,000 rods per minute
6 (with a stream height on conveyor 74 of about 120mm and rod diameters
7 of about 8mm). If the reservoir volume value exceeds the predetermined
8 value the speed of band 74 is reduced to approximately that of band 88
9 (which is itself typically determined by downstream apparatus). In this
10 condition the speed of band 74 may be progressively controlled accord-
11 ing to reservoir capacity. For example, between 85% and 95% reservoir
12 capacity the speed of the band 74 may be progressively reduced, eg
13 from a value corresponding to 5% in excess of the speed of band 88 to a
14 value corresponding to 5% less than that of the band 88. If the reservoir
15 volume value exceeds 95% capacity the band 74 will be stopped. During
16 all of this time (while the detector 92 detects articles), the speed of bands
17 70 is 55% of that of the band 74 for the time being.

18 As soon as detector 92 is uncovered, indicating that the tray at
19 unloading position 10A has typically unloaded 80% of its contents, the
20 speed of band 74 is fixed (eg at a rate corresponding to 12,000 rods per
21 minute for filter rods as mentioned hereinbefore). In this condition, ie with
22 detector 92 uncovered, bands 70 run slightly faster than band 74, eg at
23 105% of the speed of band 74. Once this final stage of unloading of a
24 tray at the unloading position 10A has started, bands 70 and 74 run at
25 these speeds until detector 94 is uncovered, irrespective of the capacity
26 of reservoir 76. When detector 94 is uncovered the band 74 is stopped
27 and the bands 70 run for a predetermined short additional time (eg 0.5
28 seconds) before stopping also.

1 In a preferred mode of operation the speed of band 74 is
2 controlled according to the angular position (Θ , Figure 5) of the pivoted
3 plate 82. Thus, where Θ is in the following ranges the speed of band 74
4 is as indicated:

5	0° - 17°	Stopped;
6	18° - 69°	High speed (eg corresponding to 48,000 cpm);
7	70° - 79°	Controlled speed based on speed of band 88 (eg pro-
8		gressively reducing from above to below speed of band
9		88);
10	80° - 90°	Stopped (unless detector 92 is uncovered);
11		Low speed (eg corresponding to 12,000 cpm) if detector
12		92 is uncovered and detector 94 covered;
13	90°	Stopped - reservoir 76 is in a jam condition (fault).

14
15 Under normal running conditions the reservoir 76 is never allowed
16 to fill such that the angle Θ exceeds 80°. This provides enough remain-
17 ing capacity (with Θ between 80° and 90°) so that if the downstream
18 demand for articles stops just as detector 92 is uncovered (so that band
19 88 is stopped) there is enough remaining room in the reservoir 76 to
20 accept all remaining articles unloaded from a tray 10 in the unloading
21 position 10A in a controlled manner.

22 Subsequently the empty tray is removed and a new full tray
23 moved into position 10A as hereinbefore described. On retraction of the
24 release plate 40 articles in the new full tray have a minimum distance to
25 fall (eg a few millimetres maximum) onto the bands 70 and the articles at
26 the top of the channel 72. During the tray change the bands 70 and 74
27 remain stationary so that the level of articles in the channel 72 remains
28 approximately the same as that of the bands 70.

THIS PAGE BLANK (USPTO)

FIG. 10 is a perspective view of the device 100, showing the top surface 66 and the circular opening 12. The device 100 is shown from a side-on perspective, highlighting the top surface 66 and the circular opening 12. The top surface 66 is a flat, rectangular area, and the circular opening 12 is a circular hole in the center of the top surface 66. The device 100 is shown in a perspective view, with the top surface 66 and the circular opening 12 clearly visible.
